# 1 Introduction

 ${\it CL\text{-}DOCWEAVER}$  is a document weaver for Common Lisp.

Documentation for a Lisp project is written with the user's tool of choice (like Texinfo, Markdown, etc). Then, Common Lisp definitions are expanded into the documentation source using DocWeaver commands.

DocWeaver commands give the user control on how definitions are to be expanded, either via command options or by choosing a different set of commands.

CL-DOCWEAVER is easy to extend to support different documentation tools.

Texinfo and Markdown are the ones with best support at this moment.

# 2 Installation

## 3 Usage

Write documentation for your Common Lisp project in your documentation tool of your choice (either Texinfo or Markdown at this moment). Then invoke *cl-docweaver* commands to expand Lisp definitions for either variables, functions, macros, classes, or even whole packages.

Commands have the following syntax: (@command-name &rest args).

For example, use (@clfunction alexandria:flatten) to expand the definition of ALEXANDRIA:FLATTEN function.

The expanded function definition expands to this:

FLATTEN (tree) [ALEXANDRIA]

Traverses the tree in order, collecting non-null leaves into a list.

Note that commands usually receive options in order to be able to control different aspects of the expanded definition.

By default, docstrings are interpreted to extract possible references to other parts of the code; then those references are formatted as links that can be used to navigate the definitions documentations.

Finally, use See [DOCWEAVER:WEAVE-FILE function], page 7to weave your documentation system source files.

Have a look at *cl-docweaver* documentation in **docs** directory for an example of how all this works.

### 4 Commands

### @setup (&rest options)

[Command]

Configures *cl-docweaver*.

OPTIONS is a plist with members:

- :docsystem The documentation system to use. Either :texinfo or :markdown. Default is :texinfo.
- :parse-docstrings A boolean that indicates if docstrings should be parsed or not. Default is T.
- :command-prefix The prefix character to use for commands. Default is the #\@ character.

### @clvariable (function-symbol &rest args)

[Command]

Expands definition for variable bound to FUNCTION-SYMBOL.

For example,

(@clvariable cl:\*standard-output\*)

Expands to this:

### \*STANDARD-OUTPUT\*

[COMMON-LISP]

default output stream

### Oclfunction (function-symbol &rest args)

[Command]

Expands definition for function bound to FUNCTION-SYMBOL.

For example,

(@clfunction alexandria:map-permutations)

Expands to this:

MAP-PERMUTATIONS (function sequence & key (start 0) end [ALEXANDRIA] length (copy t))

Calls function with each permutation of LENGTH constructable from the subsequence of SEQUENCE delimited by START and END. START defaults to 0, END to length of the sequence, and LENGTH to the length of the delimited subsequence.

Expands definition for Common Lisp package named PACKAGE-NAME.

If INCLUDE-EXTERNAL-DEFINITIONS is T, then all package external definitions are expanded.

If INCLUDE-INTERNAL-DEFINITIONS is T, then all package internals definitions are expanded.

If CATEGORIZED is T, then package definitions appear categorized in sections (variables, functions, etc).

Example:

(@clpackage :alexandria)

### @clref (symbol type)

[Command]

Creates a reference to SYMBOL. TYPE should be one of variable, function, class, etc.

For example, to reference ALEXANDRIA:FLATTEN function, do this:

(@clref alexandria:flatten function)

And this is the resulting link: See [ALEXANDRIA:FLATTEN function], page 3

# 5 Documentation systems

### 5.1 Texinfo

The Texinfo output needs to include common-lisp.texi file, that is shipped with *CL-DOCWEAVER*.

The common-lisp.texi file contains a set of Texinfo macros that are used by *CL-DOCWEAVER* for expanding Common Lisp definitions.

You can have a look at *CL-DOCWEAVER* own documentation in docs/cl-docweaver.texi for an example for how this should be used.

Also you may want to invoke makeinfo and texi2any Texinfo commands with --no-validate option, as some of the generated references in docstrings may not appear in your final document, and without that option you would get an error.

See docs/Makefile in *CL-DOCWEAVER* source for an example of how Texinfo tools should be used.

### 6 API

DOCWEAVER [PACKAGE]

### External definitions

### **Functions**

WEAVE-FILE (file output-file &rest options &key docsystem [DOCWEAVER] modules command-prefix (parse-docstrings t))
Weaves documentation source in FILE and writes the result to OUTPUT-FILE.

### Arguments:

- DOCSYSTEM: specify the documentation tool that is being used (:texinfo, :markdown, etc.).
- MODULES: is the list of *modules* (or ASDF system names) that need to be loaded to be able to read definition descriptions.
- COMMAND-PREFIX: is the character to use as prefix for commands. The character 'at' is the default.
- PARSE-DOCSTRINGS: if T, then docstings are parsed and highlighted and references to code from it created.
